Intelligent Systems for Pattern Recognition (ISPR)

# Boltzmann Machines

An example of **Markov Random Field**

- Visible RV  $\mathbf{v} \in \{0, 1\}$
- Latent RV  $\mathbf{h} \in \{0, 1\}$
- $\mathbf{s} = [\mathbf{v}\mathbf{h}]$

- A linear energy function

$$E(\mathbf{s}) = -\frac{1}{2} \sum_{ij} M_{ij} s_i s_j - \sum_j b_j s_j = -\frac{1}{2} \mathbf{s}^T \mathbf{M} \mathbf{s} - \mathbf{b}^T \mathbf{s}$$

with **symmetric and no self-recurrent** connectivity

- Model parameters  $\theta = \{\mathbf{M}, \mathbf{b}\}$  **encode the interactions** between the variables (observable and not)

Boltzmann machines are a type of **Recurrent Neural Network**

# Boltzmann Machines and Stochastic Networks

- A neural network of units whose activation is determined by a **stochastic function**
  - The state of a unit at a given timestep is **sampled** from a given **probability distribution**
  - The network learns a probability distribution  $P(\mathbf{V})$  from the training patterns

- Network includes both **visible v** and **hidden h** units
- Network activity is a sample from **posterior probability given inputs** (visible data)

# Stochastic Binary Neurons

- Spiking point neuron with **binary output**  $s_j$
- Typically **discrete time** model with time into small  $\Delta t$  intervals
- At each time interval ( $t + 1 \equiv t + \Delta t$ ), the neuron can **emit a spike with probability**  $p_j^{(t)}$

$$s_j^{(t)} = \begin{cases} 1, & \text{with probability } p_j^{(t)} \\ 0, & \text{with probability } 1 - p_j^{(t)} \end{cases}$$

The key is in the definition of the spiking probability (needs to be a function of **local potential**  $x_j$ )

$$p_j^{(t)} \approx \sigma(x_j^{(t)})$$

# General Sigmoidal Stochastic Binary Network

Network of  $N$  neurons with binary activation  $s_j$

- Weight matrix  $\mathbf{M} = [M_{ij}]_{i,j \in \{1, \dots, N\}}$
- Bias vector  $\mathbf{b} = [b_j]_{j \in \{1, \dots, N\}}$

Local neuron **potential**  $x_j$  defined as usual

$$x_j^{(t+1)} = \sum_{i=1}^N M_{ij} s_i^{(t)} + b_j$$

A chosen neuron fires with spiking probability

$$p_j^{(t+1)} = P(s_j^{(t+1)} = 1 | \mathbf{s}^t) = \sigma(x_j^{(t+1)}) = \frac{1}{1 + e^{-x_j^{(t+1)}}}$$

Formulation highlights **Markovian dynamics**

# Parallel Dynamics

How does the model state (activation of all neurons) evolve in time?

Assume RV to be updated in parallel every  $\Delta t$  (**Parallel dynamics**)

$$P(\mathbf{s}^{(t+1)}|\mathbf{s}^{(t)}) = \prod_{j=1}^N P(s_j^{(t+1)}|\mathbf{s}^t) = T(\mathbf{s}^{(t+1)}|\mathbf{s}^{(t)})$$

Yielding a **Markov process** for state update

$$P(\mathbf{s}^{(t+1)} = \mathbf{s}') = \sum_{\mathbf{s}} T(\mathbf{s}'|\mathbf{s})P(\mathbf{s}^{(t)} = \mathbf{s})$$

# Glauber Dynamics

- One neuron at random is chosen for update at each step (Glauber Dynamics)
- No fixed-point guarantees for  $\mathbf{s}$  but it has a stationary distribution for the network at equilibrium state when its connectivity is symmetric

Given  $F_j$  as state flip operator for  $j$ -th RV  $\mathbf{s}^{(t+1)} = F_j \mathbf{s}^{(t)}$

$$T(\mathbf{s}^{(t+1)} | \mathbf{s}^{(t)}) = \frac{1}{N} P(s_j^{(t+1)} | \mathbf{s}^t)$$

While if  $\mathbf{s}^{(t+1)} = \mathbf{s}^{(t)}$

$$T(\mathbf{s}^{(t+1)} | \mathbf{s}^{(t)}) = 1 - \frac{1}{N} \sum_j P(s_j^{(t+1)} | \mathbf{s}^t)$$

# The Boltzmann-Gibbs Distribution

Undirected connectivity enforces **detailed balance condition**

$$P(\mathbf{s})T(\mathbf{s}'|\mathbf{s}) = P(\mathbf{s}')T(\mathbf{s}|\mathbf{s}')$$

Ensures reversible transitions guaranteeing existence of equilibrium (**Boltzmann-Gibbs**) distribution

$$P_{\infty}(\mathbf{s}) = \frac{e^{-E(\mathbf{s})}}{Z}$$

where

- $E(\mathbf{s})$  is the **energy** function
- $Z = \sum_{\mathbf{s}} e^{-E(\mathbf{s})}$  is the **partition** function

# Learning

## Ackley, Hinton and Sejnowski (1985)

Boltzmann machines can be trained so that the equilibrium distribution tends towards **any arbitrary distribution across binary vectors** given samples from that distribution

A couple of simplifications to start with

- Bias **b** absorbed into weight matrix **M**
- Consider **only visible RV** **s = v**

Use probabilistic learning techniques to fit the parameters, i.e. **maximizing the log-likelihood**

$$\mathcal{L}(\mathbf{M}) = \frac{1}{L} \sum_{l=1}^L \log P(\mathbf{v}^l | \mathbf{M})$$

given the  $P$  visible training patterns  $\mathbf{v}^l$

# Gradient Approach

- First, the gradient for a single pattern

$$\frac{\partial P(\mathbf{v}|\mathbf{M})}{\partial M_{ij}} = -\langle v_i v_j \rangle + v_i v_j$$

with **free expectations**  $\langle v_i v_j \rangle = \sum_{\mathbf{v}} P(\mathbf{v}) v_i v_j$

- Then, the log-likelihood gradient

$$\frac{\partial \mathcal{L}}{\partial M_{ij}} = -\langle v_i v_j \rangle + \langle v_i v_j \rangle_c$$

with **clamped expectations**  $\langle v_i v_j \rangle_c = \frac{1}{L} \sum_{l=1}^L v_i^l v_j^l$

# A Neural Interpretation, Once Again!

It is **Hebbian learning**!

$$\underbrace{\langle v_i v_j \rangle}_\text{wake} - \underbrace{\langle v_i v_j \rangle}_\text{dream}$$

- **wake** part is the standard Hebb rule applied to the empirical distribution of data that the machine sees coming in from the outside world
- **dream** part is an **anti-hebbian term** concerning correlation between units when **generated by the internal dynamics** of the machine

Can only capture quadratic correlation!

# Learning with Hidden Variables

- To efficiently capture higher-order correlations we need to **introduce hidden RV  $\mathbf{h}$**
- Again **log-likelihood gradient ascent** ( $\mathbf{s} = [\mathbf{v}\mathbf{h}]$ )

$$\begin{aligned}\frac{\partial P(\mathbf{v}|\mathbf{M})}{\partial M_{ij}} &= \sum_{\mathbf{h}} s_i s_j P(\mathbf{h}|\mathbf{v}) - \sum_{\mathbf{s}} s_i s_j P(\mathbf{s}) \\ &= \langle s_i s_j \rangle_c - \langle s_i s_j \rangle\end{aligned}$$

- Expectations again become **intractable** due to the **partition function  $Z$**

# Restricted Boltzmann Machines (RBM)

A special Boltzmann machine

- Bipartite graph
- Connections only between hidden and visible units

- Energy function, highlighting bipartition in hidden (**h**) and visible (**v**) units

$$E(\mathbf{v}, \mathbf{h}) = -\mathbf{v}^T \mathbf{M} \mathbf{h} - \mathbf{b}^T \mathbf{v} - \mathbf{c}^T \mathbf{h}$$

- Learning (and inference) becomes tractable due to graph bipartition which factorizes distribution

# The RBM Catch

Hidden units are **conditionally independent** given visible units,  
and **viceversa**

$$P(h_j|\mathbf{v}) = \sigma\left(\sum_i M_{ij} v_i + c_j\right)$$

$$P(v_i|\mathbf{h}) = \sigma\left(\sum_j M_{ij} h_j + b_i\right)$$

They can be updated in batch!

# Training Restricted Boltzmann Machines

Again by likelihood maximization, yields

$$\frac{\partial \mathcal{L}}{\partial M_{ij}} = \underbrace{\langle v_i h_j \rangle_c}_{\text{data}} - \underbrace{\langle v_i h_j \rangle}_{\text{model}}$$

A Gibbs sampling approach

Wake

- Clamp data on  $\mathbf{v}$
- Sample  $v_i h_j$  for all pairs of connected units
- Repeat for all elements of dataset

Dream

- Don't clamp units
- Let network reach equilibrium
- Sample  $v_i h_j$  for all pairs of connected units
- Repeat many times to get a good estimate

# Gibbs-Sampling RBM

$$\frac{\partial \mathcal{L}}{\partial M_{ij}} = \underbrace{\langle v_i h_j \rangle_c}_{\text{data}} - \underbrace{\langle v_i h_j \rangle}_{\text{model}}$$

It is difficult to obtain an unbiased sample of the second term

# Gibbs-Sampling RBM

## Plugging-in Data

- 1 Start with a **training vector on the visible** units
- 2 **Alternate** between updating all the hidden units in parallel and updating all the visible units in parallel (**iterate**)

$$\frac{\partial \mathcal{L}}{\partial M_{ij}} = \underbrace{\langle v_i h_j \rangle_0}_{\text{data}} - \underbrace{\langle v_i h_j \rangle_\infty}_{\text{model}}$$

# Contrastive-Divergence Learning

Gibbs sampling can be painfully slow to converge

- 1 Clamp a training vector  $\mathbf{v}^i$  on **visible units**
- 2 Update **all hidden** units in parallel
- 3 Update the all visible units in parallel to get a **reconstruction**
- 4 Update the hidden units again

$$\underbrace{\langle v_i h_j \rangle_0}_{\text{data}} - \underbrace{\langle v_i h_j \rangle_1}_{\text{reconstruction}}$$

# What does Contrastive Divergence Learn?

- A very **crude approximation** of the gradient of the **log-likelihood**
  - It does not even follow the gradient closely
- **More closely approximating** the gradient of a objective function called the **Contrastive Divergence**
  - It ignores one tricky term in this objective function so it is not even following that gradient
- Sutskever and Tieleman (2010) have shown that it is **not following the gradient of any function**

# So Why Using it?

Because He says so!

It works well enough in many significant applications

# RBM-CD in Code

```
for epoch = 1:maxepoch

%— Compute wake part
data = dataOr > rand(size(data)); %Stochastic clamped input
poshidP = 1./(1 + exp(-data*W - bh)); %Hidden activation probability
wake = data' * poshidP;
%Alternatively: wake = data' * (poshidP > rand(size(poshidP)));

%—Compute dream part
poshidS = poshidP > rand(size(poshidP)); %Stochastic hidden activation
reconDataP = 1./(1 + exp(-poshidS*W' - bv)); %Data reconstruction probability
reconData = reconDataP > rand(size(data)); %Stochastic reconstructed data
neghidP = 1./(1 + exp(-reconData*W - bh));
dream = reconData'*neghidP;
%Alternatively: dream = reconData'*(neghidP > rand(size(neghidP)));

%Reconstruction error
err= sum(sum( (data-negdata).^2 ));

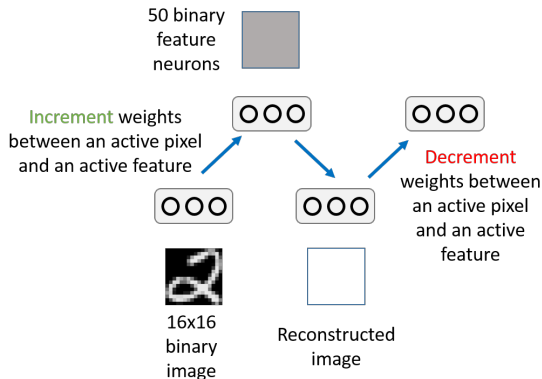

%—CD_1 Update
deltaW = (wake-dream)/numcases;
deltaBh = (sum(poshidP)-sum(neghidP))/numcases;
deltaBv = (sum(data)-sum(reconData))/numcases;
...
end
```

# Boltzmann Machines in Python

- Boltzmann machines implementations are available in all major deep learning libraries: Theano, Torch, Tensorflow, ...
- `sklearn.neural_network` contains an implementation of a binary RBM
- Little support in Python libraries for generative and graphical models
- Plenty of personal implementations on Github

# Character Recognition

Learning good features for reconstructing images of number 2 handwriting

# Weight Learning

# Final Weights

# Digit Reconstruction

## Digit Reconstruction (II)

What would happen if we supply the RBM with a test digit that it is not a 2?

It will try anyway to see a 2 in whatever we supply!

# One Last Final Reason for Introducing RBM

## Deep Belief Network

The fundamental building block for popular deep learning architectures (Deep RBM as well)

A network of **stacked RBM** trained layer-wise by **Contrastive Divergence** plus a supervised read-out layer

# Take Home Messages

- Boltzmann Machines
  - A first bridge between (undirected) generative models and (recurrent) neural networks
  - **Neural activity** regulated by stochastic behavior
  - Training has both a ML and an **Hebbian** interpretation
  - Require approximations for computational tractability
- Restricted Boltzmann Machines
  - Tractable model thanks to **bipartite connectivity**
  - Trained by a very short Gibbs sampling (**contrastive divergence**)
  - Can be very powerful if **stacked** (deep learning)
